References

- This course provides an introduction to Generalized Linear Model (GLM) and Generalized Linear Mixed Model (GLMM)
 - Mathematical background
 - Intuition and conceptualization
 - Geometrical interpretation
 - Common issues and solutions for GLM and GLMM analyses
 - Relation to ANOVA
- We will learn
 - how to conduct, interpret and report GLM and GLMM analyses in R
 - how to visualize data in R
 - how to prepare data for visualization and analysis (transformation)
 - The course will be part lecture, part learning by doing.

Lecture 1:

- (re-)introducing **Generalized Linear Models (GLM)**
- relation between GLM and **ANOVA**
- example (linear) models and geometric interpretation

Lecture 1:

- (re-)introducing **Generalized Linear Models (GLM)**
- relation between GLM and **ANOVA**
- example (linear) models and geometric interpretation

Lecture 2:

- **Generalized Linear Mixed Models (GLMM)**
- relation between GLMM and ANOVA
- random effects
- example models

Lecture 3: Beyond linear models

- Binomial models (logistic regression and mixed logit models)
- Empirical logit weighted linear regression
- Poisson models

Lecture 3: Beyond linear models

- Binomial models (logistic regression and mixed logit models)
- Empirical logit weighted linear regression
- Poisson models

Lecture 4: Tools for data analysis, exploration, and transformation

- Being able to summarize and understand your data is crucial (perhaps more important than knowing fancy models)
 - `library plyr`
 - `library reshape2`

Course overview

Lecture 5: Visualizing and summarizing your data

● library ggplot2

Course overview

Lecture 5: Visualizing and summarizing your data

- library ggplot2

Table: Example Stargazer table generated from R

	Dependent variable:		
	(logged) RT		Correct response?
	OLS	logistic	
	(1)	(2)	(3)
Intercept	6.497*** (0.030)	6.466*** (0.028)	1.664** (0.666)
Word frequency (logged)	-0.031*** (0.006)	-0.031*** (0.006)	0.412*** (0.154)
Native language	0.285*** (0.042)	0.286*** (0.042)	-1.642* (0.886)
Trial position	-0.0003** (0.0001)		
Word frequency (logged):Native language	-0.027*** (0.009)	-0.027*** (0.009)	0.261 (0.212)
Observations	1,659	1,659	1,659
R ²	0.161	0.158	
Adjusted R ²	0.159	0.157	
Akaike Inf. Crit.			520.100

Note:

*p<0.1; **p<0.05; ***p<0.01

- library stargazer
- library knitr

Lecture 6 and 7: Common issues and solutions in GLMs and GLMMs

- collinearity
- model evaluation
- over-fitting
- non-linearities

Lecture 6 and 7: Common issues and solutions in GLMs and GLMMs

- collinearity
- model evaluation
- over-fitting
- non-linearities

Lecture 8: Remaining issues and continued discussion

- Reporting GLMMs in your article

Oh, we are all so different ...

Folks in this class represent varied linguistic interest and varied degrees of expertise in statistics and R.

- The slides for this class include (usually modified) materials prepared by:
 - Judith Degen (Rochester)
 - Maureen Gillespie (New Hampshire)
 - Dave Kleinschmidt (Rochester)
 - Victor Kuperman (Stanford)
 - Roger Levy (UCSD)
- ... with their permission
- I am also grateful for feedback from:
 - Austin Frank (Rochester)
 - Previous audiences to similar workshops at CUNY, Haskins, Rochester, Buffalo, UCSD, MIT, Iowa, and Groningen.

- Throughout this class, I'll be using **R** to illustrate statistical concepts.
- It's highly recommended that you use the code on these slides to follow along, **but don't loose track of the bigger picture** (i.e., continue to listen). If necessary, tell me to slow down.
- Occasionally, you will get stuck on something. Be willing to let go. Otherwise you miss most of the class.

- The LSA and UMich organizational staff has kindly set up R and RStudio for you. **RStudio** is a work environment that combines working in R with several conveniences.

Task

Let's take a couple of minutes to familiarize ourselves with RStudio (**start RStudio**).

- The windows:
 - R script window
 - R console
 - Workspace (objects, functions, etc. you've loaded) and history of commands
 - Help, plots, files (browse directories), packages/libraries (1-click load, install, update)

- The windows:
 - R script window
 - R console
 - Workspace (objects, functions, etc. you've loaded) and history of commands
 - Help, plots, files (browse directories), packages/libraries (1-click load, install, update)
- Loading, saving, creating, etc. of scripts, sessions, projects (collections of files, working paths, defaults, etc.)

- The windows:
 - R script window
 - R console
 - Workspace (objects, functions, etc. you've loaded) and history of commands
 - Help, plots, files (browse directories), packages/libraries (1-click load, install, update)
- Loading, saving, creating, etc. of scripts, sessions, projects (collections of files, working paths, defaults, etc.)
- Loading and displaying of data files

- The windows:
 - R script window
 - R console
 - Workspace (objects, functions, etc. you've loaded) and history of commands
 - Help, plots, files (browse directories), packages/libraries (1-click load, install, update)
- Loading, saving, creating, etc. of scripts, sessions, projects (collections of files, working paths, defaults, etc.)
- Loading and displaying of data files
- Understands and compiles R, Latex, Sweave, and Knitr (e.g., from Rnw file to PDF)

- The windows:
 - R script window
 - R console
 - Workspace (objects, functions, etc. you've loaded) and history of commands
 - Help, plots, files (browse directories), packages/libraries (1-click load, install, update)
- Loading, saving, creating, etc. of scripts, sessions, projects (collections of files, working paths, defaults, etc.)
- Loading and displaying of data files
- Understands and compiles R, Latex, Sweave, and Knitr (e.g., from Rnw file to PDF)
- Code highlighting, auto-completion of commands, options, etc.

References

- If Latex (a typesetting language) is installed on your computer and the `knitr` package (a sweaving language) is installed in R (the latter can be done through RStudio), RStudio understands Latex documents with R code.
- That is you go from Latex to PDF and knitr interprets the R code in the document, automatically creating and inserting tables, figures, models, etc. into your PDF.

- If Latex (a typesetting language) is installed on your computer and the `knitr` package (a sweaving language) is installed in R (the latter can be done through RStudio), RStudio understands Latex documents with R code.
- That is you go from Latex to PDF and knitr interprets the R code in the document, automatically creating and inserting tables, figures, models, etc. into your PDF.

Demonstration

Time permitting, we'll learn more about that in a later lecture. But here's a quick demonstration.

- (Baayen, 2008): lots of useful tools, data sets, and examples directed at *linguists*; comes with its own library, `languageR`
- (Vasishth & Broe, 2011): a simulation-based approach to statistics that builds up to GLM, though it's not focused on it; great in providing deep intuitions about statistical methods (e.g., what *is* the central limit theorem? etc.); comes with R code for simulations.
- (Harrell, 2001): an amazing concepts and recipe book, which –among many other things– provides guidance and principles for model building and comparison, the assessment of non-linear relations, etc.; not directed at beginners, but also not purely technical; Harrell is a very influential regression statistician; he is also the developer of `Design` (now `rms`), an R library for running, validating, and evaluating GLMs

LINEAR REGRESSION, which underlies ANOVA, is a kind of generalized linear model.

- The predicted mean is just the linear predictor:

$$\eta = I(\mu) = \mu$$

- Noise is normally (=Gaussian) distributed around 0 with standard deviation σ_ϵ :

$$\epsilon \sim N(0, \sigma_\epsilon)$$

- This gives us the traditional linear regression equation:

$$\mathbf{y} = \underbrace{\alpha + \beta_1 \mathbf{x}_1 + \cdots + \beta_n \mathbf{x}_n}_{\text{Predicted Mean } \mu = \eta} + \underbrace{\epsilon}_{\text{Noise } \sim N(0, \sigma_\epsilon)}$$

Other common notations of the linear model

- To refer to individual data points (or simply to highlight the fact that, e.g., \mathbf{y} is a vector), we sometimes write:

$$\mathbf{y}_i = \alpha + \beta_1 \mathbf{x}_{1,i} + \cdots + \beta_n \mathbf{x}_{n,i} + \epsilon_i, \epsilon_i \sim N(0, \sigma_\epsilon)$$

Other common notations of the linear model

- To refer to individual data points (or simply to highlight the fact that, e.g., \mathbf{y} is a vector), we sometimes write:

$$\mathbf{y}_i = \alpha + \beta_1 \mathbf{x}_{1,i} + \cdots + \beta_n \mathbf{x}_{n,i} + \epsilon_i, \epsilon_i \sim N(0, \sigma_\epsilon)$$

NB: $\mathbf{y}, \mathbf{x}_1, \dots, \mathbf{x}_n$ are vectors of equal length that together constitute the data.

- To refer to individual data points (or simply to highlight the fact that, e.g., \mathbf{y} is a vector), we sometimes write:

$$\mathbf{y}_i = \alpha + \beta_1 \mathbf{x}_{1,i} + \cdots + \beta_n \mathbf{x}_{n,i} + \epsilon_i, \epsilon_i \sim N(0, \sigma_\epsilon)$$

NB: $\mathbf{y}, \mathbf{x}_1, \dots, \mathbf{x}_n$ are vectors of equal length that together constitute the data.

- Instead of α , we sometimes write β_0 or even $\beta_0 X_0$, where X_0 is assumed to be a vector of 1s:

$$\mathbf{y} = \beta_0 \mathbf{x}_0 + \beta_1 \mathbf{x}_1 + \cdots + \beta_n \mathbf{x}_n + \epsilon, \epsilon \sim N(0, \sigma_\epsilon)$$

... or in matrix notation:

$$\mathbf{y} = \mathbf{X}\beta + \epsilon, \epsilon \sim N(0, \sigma_\epsilon)$$

... where the columns of \mathbf{X} are the vectors $\mathbf{x}_0, \dots, \mathbf{x}_n$, and β is a vector consisting of β_0, \dots, β_n .

(taken from Qian & Jaeger, 2012)

Task

- Calculate the predictions of the linear combination $\beta_0 + \beta_1 x_1$, where the two **coefficients/parameters** are $\beta_0 = 5$ and $\beta_1 = .1$ and the **predictor** x_1 is SIId (the position of a sentence in a discourse). (btw, this is what `predict(model)` does in R)

Task (5mins)

- Load the data set and start exploring it.
(e.g., how many variables are in there? what do they mean? what distributions do these variables have?)

```
library(languageR)
data(lexdec)

# Try some of the following:
help(lexdec)      # learn about this R object
?lexdec          # the same
class(lexdec)     # what type of R object is lexdec?
nrow(lexdec)      # number of rows (cases)
str(lexdec)       # works on almost all R objects
summary(lexdec)   # summary of each variable in the data.frame
summary(lexdec$RT)
mean(lexdec$RT)
var(lexdec$RT)
with(lexdec, mean(RT))

# create a new data.frame that is a subset of lexdec
new = subset(lexdec, RT > 7)
nrow(new)
summary(new$RT)
```

- To that end, ...
 - we define a linear model to the data to predict (log-transformed) RTs from (log-transformed) word frequency
 - we find the parameters to this model that maximize the fit against the outcome data (i.e., minimize our prediction error against RTs). Conveniently, statistics program do these for us.
 - interpret the model and derive conclusions based on the distribution of these parameters about the significance of word frequency as a predictor of lexical decision RTs

Defining the linear model

- As a reminder here is the general formula for a linear model

$$\mathbf{y} = \underbrace{\beta_0 \mathbf{x}_0 + \dots + \beta_n \mathbf{x}_n}_{\text{Predicted Mean}} + \underbrace{\epsilon}_{\text{Noise} \sim N(0, \sigma_\epsilon)}$$

- As a reminder here is the general formula for a linear model

$$y = \overbrace{\beta_0 x_0 + \dots + \beta_n x_n}^{\text{Predicted Mean}} + \underbrace{\text{Noise} \sim N(0, \sigma_\epsilon)}_{\epsilon}$$

- For our current case with one predictor, we can thus write:

$$y = \underbrace{\beta_0}_{\text{Predicted Mean}} + \underbrace{\beta_1 x_1}_{\text{Predicted Mean}} + \underbrace{\text{Noise} \sim N(0, \sigma_\epsilon)}_{\epsilon}$$

... where β_0 is the intercept, x_1 is the predictor `Frequency` and y is the outcome RTs in the `lexdec` data (we discuss later why we include an intercept).

$$y = \overbrace{\beta_0 \mathbf{x}_0 + \dots + \beta_n \mathbf{x}_n}^{\text{Predicted Mean}} + \underbrace{\epsilon}_{\text{Noise} \sim N(0, \sigma_\epsilon)}$$

- For our current case with one predictor, we can thus write:

$$y = \underbrace{\beta_0 + \beta_1 x_1}_{\text{Predicted Mean}} + \underbrace{\epsilon}_{\text{Noise} \sim N(0, \sigma_\epsilon)}$$

... where β_0 is the intercept, x_1 is the predictor `Frequency` and y is the outcome `RTs` in the `lexdec` data (we discuss later why we include an intercept).

i.e.,

$$\text{RT} = \underbrace{\beta_0 + \beta_1 \text{Frequency}}_{\text{Predicted Mean}} + \underbrace{\epsilon}_{\text{Noise} \sim N(0, \sigma_\epsilon)}$$

Fitting the linear model

$$RT = \underbrace{\beta_0 + \beta_1 \text{Frequency}}_{\text{Predicted Mean}} + \underbrace{\epsilon}_{\text{Noise} \sim N(0, \sigma_\epsilon)}$$

- Luckily, we don't need to be Gauss to fit a linear model. We just let R (or another statistics program) fit the model to the data. For example, in R:

```
# glm() is R's call to a GLM
# 1, in an R-formula, is a specific symbol for the intercept
# Frequency and RT are variables in the data.frame lexdec
# data tells glm which data.frame to use
# family tells glm which distributions the outcome is assumed to have
m = glm(RT ~ 1 + Frequency, data = lexdec, family = gaussian)
```

$$RT = \overbrace{\beta_0 + \beta_1 \text{Frequency}}^{\text{Predicted Mean}} + \underbrace{\text{Noise} \sim N(0, \sigma_\epsilon)}_{\epsilon}$$

- Luckily, we don't need to be Gauss to fit a linear model. We just let R (or another statistics program) fit the model to the data. For example, in R:

```
# glm() is R's call to a GLM
# 1, in an R-formula, is a specific symbol for the intercept
# Frequency and RT are variables in the data.frame lexdec
# data tells glm which data.frame to use
# family tells glm which distributions the outcome is assumed to have
m = glm(RT ~ 1 + Frequency, data = lexdec, family = gaussian)
```

- This fits the coefficients/parameters, i.e.
 - the intercept β_0 ,
 - the slope of the Frequency effect β_1 , and
 - the standard deviation of the residuals σ_ϵ

... to the data, using MAXIMUM LIKELIHOOD (ML) ESTIMATION.

$$RT = \overbrace{\beta_0 + \beta_1 \text{Frequency}}^{\text{Predicted Mean}} + \underbrace{\text{Noise} \sim N(0, \sigma_\epsilon)}_{\epsilon}$$

- The ML-fitted model provides coefficient *estimates* (hence, the hat above the β s and σ), and estimates of their standard errors.
(for linear models, the analytic optimal solution is known, so these estimates are guaranteed to be optimal in that they minimize the prediction error against the known data y)

Going back to the frequency model

$$y = \underbrace{\beta_0 + \beta_1 x_1}_{\text{Predicted Mean}} + \underbrace{\epsilon}_{\text{Noise} \sim N(0, \sigma_\epsilon)}$$

- The coefficient estimate $\hat{\beta}_0$ describes the intercept (where the line cross the y-axis)
- The coefficient estimate $\hat{\beta}_1$ is our ML estimate for the *slope* of Frequency.

Interpretation: Ordinary least squares (OLS) regression

- The slope for `Frequency` (i.e., $\widehat{\beta}_1$) minimizes the sum of the squared *vertical* distances between the line and all points.

NB: The directionality in this statement is important - we are minimizing the (squared) error in predicting the *outcome* (not the distance from the line).

NB: Maximum likelihood (ML) fitting is identical to least-squared error for Gaussian errors, but ML fitting is the more general approach than this geometrical interpretation, as it extends to other types of GLMs.

Drawing inferences from the linear model

$$y = \overbrace{\beta_0 + \beta_1 x_1}^{\text{Predicted Mean}} + \underbrace{\epsilon}_{\text{Noise} \sim N(0, \sigma_\epsilon)}$$

- Based on the ML-fitted linear model, we can draw inferences about the statistical significance of word frequency as a predictor of RTs
- That is, we can draw test whether β is statistically different from 0 (the null hypothesis)
- If it is, we will reject the null hypothesis that `Frequency` has no effect on RTs (i.e, we conclude that word frequency affect lexical decision RTs).

Drawing inferences from the linear model

$$y = \overbrace{\beta_0 + \beta_1 x_1}^{\text{Predicted Mean}} + \underbrace{\epsilon}_{\text{Noise} \sim N(0, \sigma_\epsilon)}$$

- Based on the ML-fitted linear model, we can draw inferences about the statistical significance of word frequency as a predictor of RTs
- That is, we can draw test whether β is statistically different from 0 (the null hypothesis)
- If it is, we will reject the null hypothesis that `Frequency` has no effect on RTs (i.e, we conclude that word frequency affect lexical decision RTs).
- As a matter of fact, all the information we need is already there:

	Estimate	Std. Error	t value	Pr(> t)
## (Intercept)	6.5887784	0.02229593	295.51482	0.00000e+00
## Frequency	-0.0428718	0.00453251	-9.45874	1.02656e-20

Question

- What is the t -statistic based on?
- What would be an intuitive interpretation of what the t -statistic tells us?

Drawing inferences from the linear model

- The standard summary of a `glm` object already contains all this information and more:

```
summary(m)

##
## Call:
## glm(formula = RT ~ 1 + Frequency, family = gaussian, data = lexdec)
##
## Deviance Residuals:
##      Min       1Q   Median       3Q      Max
## -0.5541  -0.1615  -0.0349   0.1170   1.0877
##
## Coefficients:
##              Estimate Std. Error t value Pr(>|t|)
## (Intercept)   6.58878     0.02230   295.51  <2e-16 ***
## Frequency    -0.04287     0.00453    -9.46  <2e-16 ***
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
##
## (Dispersion parameter for gaussian family taken to be 0.0553721)
##
##      Null deviance: 96.706  on 1658  degrees of freedom
## Residual deviance: 91.752  on 1657  degrees of freedom
## AIC: -88.58
##
## Number of Fisher Scoring iterations: 2
```

So, is this the absolute truth?

- The conclusions drawn from a model are *conditional on the model we assumed!*
(that is *always* true in statistics, although we tend to forget that)
- That is, our conclusions depend on
 - the general *type* of model we used, in this case an linear model:
 - The effect of `Frequency` in RTs, i.e. that log-transformed word frequency has a linear effect (if any) on log-transformed lexical decision RTs
 - Trial-level noise is *normally distributed*, i.e. log-transformed RTs are normally distributed
 - the specific predictors in the model, in this case meaning that we assume that no factors other than `Frequency` affect RTs or that they do so in ways independent of `Frequency`

- Now that we have a good intuition about GLM, let's relate it to **Analysis of Variance (ANOVA)**
- The two methods share the goal of assessing statistical significance of one set of variables (predictors or independent variables) in the explanation of the distribution of other variables (outcomes or dependent variables).
- The two methods also share some, though not all, assumptions.
- But first a quick refresher for ANOVA (figures on next three slides are taken from Wikipedia,
https://en.wikipedia.org/wiki/Analysis_of_variance).

● Shared with ANOVA:

- Linearity assumption (though many types of non-linearity can be investigated)
- Assumption of normality, but part of a more general framework that extends to other distribution in a conceptually straightforward way.
- Assumption of independence

NB: **ANOVA** is linear model with (only) categorical predictors. An **ANCOVA** contains categorical *and* continuous predictors.

● Differences:

- **GLM** readily extends to other instances from the **exponential family** (e.g., Binomials, Poisson).
- **GLM** encourages a priori explicit coding of hypothesis.

NB: Like AN(C)OVA, the linear model assumes that the outcome is linear *in the coefficients* (**linearity assumption**).

- This does not mean that the outcome and the **input variable** have to be linearly related (cf. previous page).
- To illustrate this, consider that we can back-transform the log-transformed Frequency (as shown above)

- Typically, we make predictions not just about the existence, but also the *direction* of effects.
- Sometimes, we're also interested in effect *shapes* (non-linearities, etc.)
- Unlike in ANOVA, regression analyses reliably test hypotheses about **effect direction**, **effect shape**, and **effect size** without requiring post-hoc analyses if (a) *the predictors in the model are coded appropriately* (cf. lecture on **Coding Categorical Predictors**) and (b) *the model can be trusted* (cf. lecture on **Common Issues and Solutions in Regression**).

- Recall that we're describing the **output** as a linear combination of the **predictors**.

→ Categorical predictors need to be (re)coded numerically. (cf. **coding lecture**)

NB: The default is 'dummy'/'treatment' coding for regression, where the treatment contrasts are based on the alphabetical order of the levels of the categorical variable.

- This can be quite confusing, as in the current case, where `NativeLanguage` recoded to 1 for "Other" vs. 0 for "Native".

Predicting Lexical Decision RTs

Native Speakers (red) and
Non-Native Speakers (purple)

Interactions

- Let's test whether NativeLanguage and Frequency interact:
Perhaps non-native speakers are only slower on average because they don't know some of the words? In that case, we should see that natives and non-natives have similar RTs for high frequency words.

```
m4 = glm(RT ~
          Frequency +
          Trial +
          NativeLanguage +
          Frequency:NativeLanguage,
          data = lexdec
)
summary(m4)$coefficients
